Spacer composition, not motif arrangement, dominates apparent regulatory grammar detected by DNA foundation models

Bryan Cheng[1,*], Austin Jin[1] [1]Cold Spring Harbor Laboratory, Cold Spring Harbor, NY, USA [*]bcbc7264@gmail.com

Motivation

Whether the spatial arrangement of transcription factor (TF) binding sites encodes functional information—a "regulatory grammar"—or whether enhancers operate as "billboards" where only TF identity matters remains debated [1,2]. DNA foundation models enable systematic *in silico* perturbation of enhancer architecture, but standard grammar sensitivity metrics confound motif arrangement with spacer DNA composition. We introduce a **spacer-factored grammar sensitivity framework (SF-GSI)** applied across four foundation models, five MPRA datasets, and four organisms to quantify the true contribution of motif arrangement to gene expression.

Figure 1: Spacer composition dominates apparent grammar effects. (A) Factorial decomposition: spacer composition accounts for the majority of expression variance. **(B)** Spacer-level perturbations drive larger expression changes than motif rearrangement. **(C)** Compositional features predict 40–80% of model R^2. **(D)** GC–expression correlation reverses across species ($r = +0.63$ human vs. $r = -0.76$ plant).

Methods

Grammar Sensitivity Index (GSI). TF motifs are identified via FIMO against JASPAR 2024 [3]; 1,000 vocabulary-preserving shuffles permute motif order while holding identity constant. GSI $= \sigma(\hat{y})/|\mu(\hat{y})|$. **Spacer-Factored GSI (SF-GSI).** A factorial design isolates: (i) motif position/orientation (true grammar), (ii) spacer composition (confound), (iii) flanking-context effects via matched-spacer shuffles and regression residuals. **Rule Extraction.** Pairwise rules via spacing scans (2–50 bp), four orientation configurations, and helical phasing at ∼10.5 bp. **Variance Decomposition.** Hierarchical ANOVA: vocabulary → +grammar → +higher-order → full model. **Models & Data.** DNABERT-2, Nucleotide Transformer v2-500M (transformers), HyenaDNA (SSM), PARM (CNN); five MPRA datasets across human, yeast, and plant (∼7,650 enhancers) [4,5].

Results

The spacer confound. Spacer DNA composition accounts for 78–86% of measured GSI variance (Fig. 1A–B). Simple compositional statistics explain 40–80% of predictions (Fig. 1C), and the GC–expression relationship reverses between species (Fig. 1D).

Figure 2: Statistical correction eliminates grammar signal. (A) GSI distributions across models. **(B)** Median GSI by dataset. **(C)** Significant enhancers: 100% (naive) → 8.3% (z-score) → **0.17%** (FDR). **(D)** Cross-model agreement ($\rho \approx 0.74$).

Correction cascade. Naive testing yields 100% "grammatical" enhancers; z-score normalization reduces this to 8.3%, and FDR correction to **0.17%**—a three-order-of-magnitude drop consistent across all architectures (Fig. 2C–D).

Positive controls. With spacer composition held constant, orientation effects are detected at $p < 10^{-117}$ with 100% detection rate (vs. 8.3% under standard shuffles), confirming methodological sensitivity; the null result reflects biology.

Variance decomposition. Motif identity explains 8–22% of expression variance; grammar adds only 0–1.6% R^2. Replicate ceilings ($\sim$85% R^2) indicate most variance is attributable to *trans*-regulatory factors beyond enhancer sequence.

Figure 3: Grammar rules do not transfer across species. (A) Within-species $R^2 = 0.10$–0.21; cross-species ≈ 0. **(B)** Cohen's d: 2× larger cross-species (1.89 vs. 0.95; $p = 0.03$).

Cross-species transfer. Grammar rules from one organism predict near-zero effects in others (Fig. 3), consistent with the absence of conserved regulatory syntax.

Conclusion

Regulatory DNA operates predominantly as a *billboard*: TF identity, not arrangement, determines enhancer activity. Apparent grammar is largely spacer composition—a confound inflating sensitivity $\sim$1,000×. Findings hold across four architectures, five datasets, and four organisms. SF-GSI provides the statistical machinery to separate grammatical effects from compositional confounds in regulatory genomics. Code: `https://github.com/bryanc5864/GRAMLANG`.
